Minimum Ventilation to Maximise Broiler Farm Performance

Ing. Winfridus Bakker
Cobb-Vantress
Available Types Of Ventilation Systems
Simplified

- Natural ventilation system where the house is open.
- Positive pressure system for open and closed houses.
- Negative pressure system, by far the best design and the most efficient and economical for any poultry operation world wide.
Most birds live in highly technical houses.
## Influence of ambient Temperature on the Mortality of Chicks in 1\textsuperscript{st} wk.

Behavior of Chicks First Few Days

- The chicks behave normally when the rectal temperature is between 39.5 and 40.0°C.
- When the temperature is lower the chicks will huddle together.
- When the temperature is too high the chicks first start making a lot of noise, then open their beaks to pant. Wings will drop and the chicks will cry louder and louder. If the temperature continues to rise they will go unconscious and die when the rectal temperature gets to 44°C.
Rectal Temperature of Chicks

Ideal Temp. 39.5–40ºC

Litter Temperature at 2.5 cm below the litter surface
How to take temperatures of Chicks

- Chicks that are smaller tend to have some lower temperature at hatch.
- If the navel temperature is taken subtract 0.5°C compared to rectal temperatures (39.5-40°C).

Floor Temperature

• How hot? 40°C (Litter under brooder)
• How hot? 32°C (Litter temperature whole house with heaters)
• First 5 days is critical time (chick body temperature should rise to 40°C)

Why?
• Health/7 day mortality
• Feed intake/performance
Chilled Chicks = Lower Weights

- University of GA study
- Cold stress chicks for just 45 minutes at placement.
  - 12.8 °C = 55 °F cold environment
- Banded and mixed control and stressed chicks.
- Cold stressed chicks were significantly lighter (109 grams = 0.24 lbs) at 35 days of age.

More critical with small chicks or slightly dehydrated chicks (increased surface to weight ratio).
Effect of brooding temperature on broiler performance to 42 days

Present House Design

House height is determined by height of machines that need to enter to harvest birds, clean out the house etc.

Ideal side house opening gives air restriction for entering. Opening on opposite site is 5 times inlet opening.
Improved House Design With Drop Curtain Sidewalls At Top Of Opening For Natural Ventilation

Heat as Insulator

Positive

Higher curtain on windward side of the house.

To increase air exchange in the house without high air velocity across birds.

Negative
Improved House Design With Drop Curtain Sidewalls At Top Of Opening For Natural Ventilation

Heat as Insulator

To decrease air exchange in the house without high air velocity across birds.

Lower curtain on windward side of the house.
Improved House Design With Drop Curtain Sidewalls At Top Of Opening For Natural Ventilation

Heat as Insulator

Curtains even on both sides of the house.

To increase air exchange in the house and higher air velocity across birds.
Poultry House Ventilation Systems

1. **NATURAL VENTILATION** To be used when total mechanical ventilation is not available however should include minimum ventilation fans for early age.

2. **MINIMUM VENTILATION SYSTEM** To be used for cool weather and during brooding. Low air velocity over the birds and long air exchange rate. This system is for air quality and a slight amount of temperature control.

3. **TRANSITION VENTILATION SYSTEM** To be used to allow for a much better air exchange rate inside the house, without high air velocity across the birds, until the birds more than 28 days of age. Difficult to justify the cost compared to benefits.

4. **SUMMER VENTILATION SYSTEM** To be used for temperature control and create a high air speed (velocity) across the birds. To lower the effective temperature and reduce heat prostration.
What happens to Air Speed from a fan within the House

Loose hanging fan in the house

Very un-uniform air speed and migration of the birds occurs. Birds try to find the best environment.
Order of Best Ventilation Efficiencies of Chicken Houses

All Houses Shown Have Minimum Ventilation Going Across The house.

1-2
- Tunnel ventilation with foggers and minimum ventilation.

2-1
- Tunnel ventilation with evaporative cooling and minimum ventilation.

3
- Open wall house with positive pressure fans in sidewall at 60 degree angle.

4
- Open wall house with stir fans down the center of the house in one row.
Ventilation efficiencies continue.

5

Stir fans staggered down center of the house in two rows.
Open wall house.

6

Open wall house and hope the wind blows.

3

In mild climates

4

In hot climates

Closed cross ventilated houses with foggers.
The cone fans should be installed a minimum of 1/2 the diameter of the fan from the ground and when possible 30 inches (76 cm).
Minimum Ventilation

- Is based on negative pressure in the house to get the proper air distribution.
- Is used as a cross ventilation to keep the air speed very low or almost nil in the first 2 weeks.
- Is used to avoid chilling the chicks so that all available feed energy can go for growth and uniformity.
HOUSES IN HOT CLIMATES CAN HAVE ONE VENTILATION SYSTEM, BUT……..

- During the first 3 weeks the curtains are down and only natural ventilation is used.
- As of 21-28 days TUNNEL VENTILATION is used till the end to keep the birds cool and avoid heat prostration.
- However apply minimum ventilation concept if no optimal results are obtained with Natural Ventilation in the first 3 weeks, with negative reflection on final BW, Mortality and FCR (90% of the cases).
What is the Importance of Minimum Ventilation in Chicks?

- Minimum ventilation will guarantee that ventilation and fresh air are given to the chicks as of day old to obtain maximum growth rate and organ development in the first few weeks, critical for good end performance of the flock.
Air temperature & Air Speed
over the Chicks

- 1\textsuperscript{st} week - Still air - Max. 15 fpm. Temp. 32 °C (90 °F)
- 2\textsuperscript{d} week - Still air - Max. 30 fpm. Temp. 29 °C (84 °F)
- 3\textsuperscript{d} week - Max. 100 fpm. Effective Temp. 27 °C (81°F)
- 4\textsuperscript{th} week - Max. 200 fpm. Effective Temp. 25 °C (77 °F)
- > 28 days depending on temperature. Effective Temp. 22 °C (72 °F) and lowering to 18 °C (64 °F) > 35 days.
All fans running in the 1st week
550 fpm at 25 days of age
Cross and Tunnel Ventilation
Cross & Tunnel Ventilation Calculations

Cross ventilation: Length house $\times$ Av. Height = cross section
$400 \text{ f} \times 9 \text{ f} = 3600 \text{ f}^2$.  1 fan 36” = 11,000 cfm $\div$ 3600 $\text{f}^2 = 3 \text{ f/m}$

Tunnel ventilation: Width house $\times$ Av. Height = cross section
$40 \text{ f} \times 9 \text{ f} = 360 \text{ f}^2$.  1 fan 36” = 11,000 cfm $\div$ 360 $\text{f}^2 = 30 \text{ f/m}$
With 48” fan the air speed will increase to 21,500 cfm $\div$ 360 $\text{f}^2 = 60 \text{ f/m}$.  If larger fans are used the problem only gets worse.

Cross-Flow Ventilation With Counter Balanced Inlet For Second Stage Air Volume

COMFORTABLE ANIMALS, WARM DRY FLOORS, EVEN DISTRIBUTION OF AIR, AND LOW UTILITY COSTS
Cross-Flow Ventilation With Continuous Slot
For Second Stage Air Volume

Temperature will always increase

Comfortable Animals, Warm Dry Floors, Even Distribution of Air, Low Energy Cost
Ventilation Criteria in Sequence of Importance before 28 days of age

- Air exchange in the house. Air volume can never be compromised for temperature only.
- Pressure drop across the inlets or air cannons. Needed as an effective tool for proper air distribution and reduce heating costs.
- Air distribution. Minimum ventilation has as a rule the objective to get good warm and fresh air distribution to chicks without cooling them down.
- House temperature. Expansion of air by heat and evaporation of moisture from the air are the only two things that will keep floors dry in cold weather.
Side Fans Needed - Calculations

- Rule: Side fans runs 1 minute of every 8 minutes and then 1 minute every 5 minutes.
- Take volume house ÷ 8 = 19,000 cfm (example)
- One 36” fan rated 10,500 cfm
- 19,000 ÷ 10,500 = 2 fans
- House volume ÷ 5 = 30,400 cfm ÷ 10,500 = 3 fans in side wall.
Spacing of the side fans is important.

Take # fans and double number, so in this case 3x2=6.

Take length house = 400 f ÷ 6 = 67 feet first fan. 2d Fan at 67 x 2 = 134 f. from first and 3d fan at same distance of 134 feet from 2d.
- Take the length of the house $\div 10 + 8$.
- Example: 400 feet house $\div 10 + 8 = 48$ air cannons.
- In 4 corners 2 each = 8
- Resting 40 to be spread out over 400 feet = 1 every 10 feet.
Every air cannon has capacity of 40 cfm (2.5 “ (6.4 cm) diameter) in which air speed enters at 1100 fpm and exits at 900 fpm (difference is due to friction loss).
Transition Ventilation

- In this procedure sufficient inlet capacity is installed so that up to 21-28 days of age the birds can have proper air exchange without the excess air speed.
- With the 2 side curtains being opened for a few cm’s or when installing inlets like TJP 2155, calculate the inlet opening based on 4 fans running instead of 2 (minimum ventilation for first 14 days).
Final Thoughts

- Minimum ventilation is very important to assure the proper growth and uniformity of the broiler flocks.

- A good start (0-14 days) represents more than 50% of the success of the flock.

- Analyze your broiler results knowing weekly BW’s and mortality. With these data you should fine tune management. Minimum ventilation is a crucial part of this management.
